				FR-01 to FR-04 - zone assignment	SET-UP: FR-01 says the system stores a person's 'age or date of birth'. FR-02 assigns a zone automatically from age - Zone 1 up to 12, Zone 2 for 13 to 19, Zone 3 for 20 to 29, Zone 4 for 30 and above. FR-03 lets the administrator change those boundaries later. QUESTION: A twelve-year-old you registered last year has had a birthday. What moves them from Zone 1 to Zone 2 - and when the administrator changes a boundary, what happens to everybody already assigned?	Sees that storing a plain age instead of a date of birth makes the zone stale on the next birthday and impossible to recompute, so date of birth should be the stored value with age only as a flagged fallback. Then supplies the missing requirement: either a scheduled re-evaluation or zone computed on read. On the boundary change, asks the harder question - are existing assignments recalculated, and do the manual overrides allowed by FR-04 survive the recalculation? The best answers reach the reporting consequence: if zones are recomputed, last year's reports change retrospectively, so attendance records should store the zone as at the date of the service, not a live lookup.

				FR-33 to FR-41 - messaging consent	SET-UP: FR-33 to FR-37 send thank-you messages and reminders by email, SMS and WhatsApp to everyone whose contact details you hold, and those details come off a handwritten sign-in sheet. FR-41 lets a member be flagged so that messaging is suppressed. Section 3.4 requires compliance with applicable data protection requirements. QUESTION: Where in this system does a visitor agree to be messaged before the first thank-you goes out - and what does the WhatsApp Business API require before you may message someone?	Distinguishes opt-out, which FR-41 provides, from opt-in, which is missing entirely - writing your name on a sign-in sheet is not consent to be messaged on three channels. Knows or reasons out that the WhatsApp Business Platform requires prior opt-in obtained through a clear channel, with business-initiated messages sent as approved templates. Proposes capturing consent per channel at registration, storing the date and source of consent, a requirement forbidding messaging without recorded consent, and an unsubscribe route in the message itself. Strong answers notice the tension with 2.4: consent would naturally be captured on the sign-in sheet, which the client has fixed, so this needs to go on the open-items list in 3.6.3.

				FR-15 and 3.5.1 - working without a connection	SET-UP: Section 2.4 says connectivity at outlying campuses may be limited. FR-15 says the system shall preserve entries made in an attendance session if the connection is interrupted, and allow the session to be resumed. Section 3.5.1 repeats the promise. QUESTION: Where are those entries held while the connection is down, and what happens if the session is resumed later on a different computer?	Recognises that the requirement states an outcome with no mechanism behind it anywhere in the document, and that this is the gap. Names the realistic options - local storage on the client with a sync step on reconnect, versus server-side draft sessions, which cannot help because saving needs the connection - and then specifies what the missing requirements must cover: how long unsynced entries may persist, what the user sees, what happens if the same service is entered on two machines, and how the sync resolves it. The strongest answer spots that FR-14's duplicate rejection depends on the server, so duplicates cannot be detected at all while offline, and the sync step must therefore do the duplicate check.

				3.5.3 Security and 3.6.3 - sensitive data	SET-UP: This system links a named person to their religious attendance and to the amounts of money they give. Section 3.5.3 says member contact details shall be stored and transmitted securely and that offering data is restricted to users with financial permissions. Section 3.6.3 lists the retention policy as still to be confirmed. QUESTION: For data this sensitive, what is missing from your security section - and how long should a record of what a named person gave be kept?	Recognises that 'securely' names no standard, and supplies the specifics: a named TLS version in transit, encryption at rest for offering and contact data, and an authentication policy, since FR-48 requires authentication but nothing states password rules, lockout, session timeout or whether the administrator account needs stronger protection. On retention: a stated period per data class, a rule for a member who leaves the church, and the observation that 3.3.2 already assumes 10 years online without any requirement to archive or purge afterwards. Strong answers note that the audit log in 3.5.3 records changes and denied attempts but not who READ giving data, which for this dataset is the access most worth logging.

				3.3 and 3.5 - shall versus should	SET-UP: Your forty-eight functional requirements are disciplined 'the system shall' statements. But your whole performance section uses 'should' - searches should return within 1 second, reports should generate within 20 seconds - and sections 3.1.1 and 3.5 mix 'should' and 'must'. QUESTION: If the delivered system takes 4 seconds to return a search, has it broken any requirement in this document - and what exactly would you change?	Explains that 'shall' binds and 'should' is advisory, so as drafted a supplier could miss every performance target in section 3.3 and still claim compliance - which is a shame precisely because those targets are the best written in the class, with percentiles and a stated measurement basis. Proposes converting 3.3 and 3.5 to 'shall' wherever the team means the target to be binding, keeping 'should' only where they genuinely mean a preference, and stating the convention once in section 1 so a reader knows what each verb means. Strong answers spot 'must' in 3.1.1 as a third form and note that three verbs for two meanings is worse than two.

				FR-44 and 2.3 - one role per user	SET-UP: FR-44 says the system shall assign each user exactly one role: System Administrator, RFP Staff, or Access Control Team. But section 2.3 says the Access Control Team also assists with attendance entry, FR-23 bars them from offering data, and section 3.6.3 admits the detailed access restrictions per role are still only a proposal. QUESTION: At a small campus, one volunteer receives people, enters the attendance afterwards, and sometimes helps with the offering count. How does your model handle her - and what would you change if the client says one person	Sees that a strict one-role model forces a bad choice: give her the Staff role and she gains financial access that FR-23 is meant to deny ushers, or leave her as Access Control Team and she cannot do the job she actually does. Offers a workable alternative - multiple roles per user, or roles composed from permission sets - and notices that FR-45 already provides campus and service scoping, so the building blocks exist. Best answers add that segregation of duties matters for money: whoever enters an offering arguably should not be the only person able to amend it, which FR-22 currently permits, and that this belongs on the 3.6.3 list which already flags an approval step as an open question.

				Diagrams, data model and document control	SET-UP: Your use cases are written out fully in words - actor, precondition, main flow, exception scenarios - which no other group did. But there is no diagram anywhere in the document: no context diagram, no use-case diagram, no data model. The document carries version 3.0 in the footer but no date, no author responsibilities, no reviewer and no revision history, and the seven open items in 3.6.3 have no owner or deadline against them. QUESTION: Draw the data model for this system on the board - the main entities and how they relate - and then tell me what should sit beside each of	Draws Member/Visitor, Campus, Service, Attendance, Offering, Zone, User and Message Log with sensible cardinalities: a member has many attendance records, an attendance belongs to one member and one service, a service belongs to one campus, and an offering links a member to a service, which is exactly what FR-20 requires. Ideally notices that drawing it raises questions the prose left open - whether zone is a stored attribute or derived, and whether an attendance record points at the member's home campus or the campus where the service happened. On the open items: an owner, a target date, and a note of which requirements change if the answer changes - plus a revision history, so that 'version 3.0' can be reconciled
